TREATMENT MYTHS DISPELLED

If you are one of the approximately 80 million Americans suffering from varicose veins and related vein disorders, I have good news for you.

The past 10 years have seen revolutionary advances in the treatment of varicose veins. It is no longer necessary to endure painful vein stripping and vein removal procedures done in the hospital, which required prolonged recovery times. New state-of-the-art vein treatments are relatively painless, can be done in an office setting, involve minimal or no down time and allow almost immediate return to work and activities.

As with many new medical advances, the awareness and understanding of these treatment options lags behind the technology. In an effort to help bridge the gap of understanding, a brief explanation of veins is needed followed by a discussion of some of

the most common misconceptions I encounter regarding vein disease and vein treatments.

How do veins work and what are varicose veins?

Veins are blood vessels which return blood to the heart and lungs so it can be re-oxygenated. This means blood in the veins should move up and out of the legs toward the heart. There are a series of

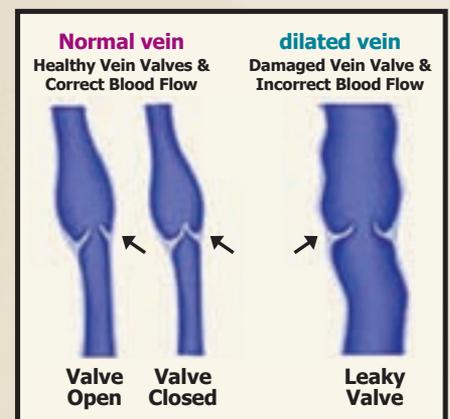

one-way check valves in the veins which prevent the backward flow of blood toward the feet.

When the one way valves fail or leak, gravity causes blood to flow backwards towards the feet and pool inside the veins. This backward flow of blood is called venous reflux or venous insufficiency. Over time, the pooling blood leads to excess pressure in the veins causing them to stretch and dilate.

While varicose veins are unsightly, they are also an indication of a more

significant venous insufficiency disorder affecting veins below the skin which cannot be seen with the naked eye. Visible signs of venous insufficiency include swollen legs or ankles (especially with prolonged standing or sitting), large bulgy varicose veins, clusters of small red or purple starburst appearing veins (spider veins), color and texture changes of the skin on the legs and open sores in severe cases. Leg pain, aching, tired or weak legs (especially after long periods of standing or sitting), restless legs, leg cramps and burning or itching of the skin are all symptoms which might reflect venous disease.

The cause of venous insufficiency is not yet fully understood; however, heredity plays an important part of this disorder. If one parent had venous

disease, the chance of developing it is almost 50 percent. If both parents have venous disease, there is almost a 90 percent chance of developing the disorder. Other factors which play a role in the development of venous insufficiency include excessive body weight, prolonged standing or sitting, pregnancy, hormonal changes and hormone replacement, advancing age or injury to the veins themselves.

MYTH: Varicose veins are only a cosmetic problem

The American College of Phlebology estimates that varicose veins and related vein disorders affect over 80 million Americans. These disorders can increase the risk of developing life threatening blood clots, cause open wounds on the legs, cause significant leg swelling, pain, discomfort and impair quality of life. The good news is varicose veins and vein disorders are highly manageable conditions.

MYTH: Leg discomfort and varicose veins are a normal part of the aging process

Leg discomfort and varicose veins are not normal at any age; however, varicose veins and vein disorders do worsen with age. If you suffer from heaviness, aching, swelling or fatigue of the legs and/or varicose veins, you should be evaluated by a vein specialist.

MYTH: Crossing your legs can cause varicose veins

Sitting for prolonged periods of time in any position can increase your risk of varicose veins; however, there is no medical research to support that periodic crossing of the legs causes varicose veins.

MYTH: There are herbal remedies which can help varicose veins

There might be some truth to this; however, it must be interpreted with

caution. There is limited evidence to suggest that horse chestnut seed extract might improve some of the symptoms associated with varicose veins such as swelling, pain and itching, but it does not treat the underlying vein disorder. Any symptom improvement experienced while taking the herb typically returns again immediately upon cessation and it does not prevent vein disorders from worsening. This herb can be expensive and has a very limited place in the management of varicose veins. Taking it should never replace formal evaluation and treatment by an experienced vein specialist.

MYTH: Vein treatments do not work—the varicose veins just come back later

Effective treatment starts with proper identification of the source of varicose

veins. Accurate identification of vein disease and its treatment have improved considerably over the past 10 to 15 years. The advanced treatment techniques used today—when paired with accurate disease identification—are far more effective in preventing a recurrence of varicose veins than the older methods. Although occasional follow-up treatments might be required, most patients have good long-term results.

MYTH: Sun exposure causes varicose veins

Although exposure to UV light, either from the sun or tanning lights, probably does not increase the risk of leg vein disorders, it can contribute to the development of spider veins on the face and cause certain types of skin cancers.

MYTH: Treatments for varicose veins leave scars and are really painful

The older methods of vein treatments often required hospitalization, were notoriously painful and frequently left large scars; however, the new minimally invasive techniques can be done in the office, involve little discomfort and leave minimal scars—even in the most advanced cases of varicose veins. These newer vein treatments typically

Unsightly, Painful

Varicose & Spider Veins?

We can help!

- All diagnosis and treatment done in the comfort of our office
- Quickly return to work and activities
- Personalized treatment plans
- Covered by most insurances

EXPERT VEIN CARE at a practice devoted exclusively to state of the art vein diagnosis and treatment.

“The Home of Happy Legs”[®]
a division of Premier Surgical of WI, S.C.

Leanna L. Beaumont, MSN, APNP

include a combination of laser closure of veins, injection of unhealthy veins and mini vein removal procedures.

MYTH: Vein treatments require long and painful recoveries

Recovery from the older treatment techniques, which involved hospitalization and general anesthesia, took much longer and was much more uncomfortable. Resumption of daily activities took anywhere from four to six weeks. The newer, minimally invasive treatments are done in an office setting with local anesthesia, so most people resume normal activities the same day with minimal discomfort.

MYTH: Vein treatments are expensive and insurance does not cover them

The cost of vein treatments has actually been reduced by the

new technology. Advanced vein treatments can be performed in an office setting without the need for general anesthesia. This eliminates hospital charges and anesthesia fees, significantly reducing the overall cost to patients and insurances. In addition, varicose veins and related vein disorders can cause painful and debilitating symptoms making them much more than a "cosmetic" issue, so most insurances do cover vein treatments. Although spider vein treatments are not covered by insurances, they have also become much more affordable with the latest treatment advances.

It is important that you are proactive with this information. Evaluation and treatment are safe, effective and affordable when done at an experienced vein treatment center. So don't wait, seek help at a vein center near you. ■
